**Version: 4.2.2**

Managing Filters and Filter Source Type

`Article` `08/22/2023`

You can manage filters from the 'Filtering options' in the ribbon. This will pop up a panel where you can create, edit, or remove your filters defined in your model. This intuitive interface ensures that you have full control over your data filtering process.

dReveal offers various filter types to cater to different data filtering needs. Understanding these filter types and their usage can greatly enhance your reporting experience. In this guide, we'll explore the three main filter types: None, SQL, and Hierarchical.

None Filter Type

The **None filter type** allows users to provide native inputs, such as dates, numerics, and string selections, directly. This type of filter is ideal when users need to specify specific values without relying on predefined lists or structures.

SQL Filter Type

The **SQL filter type** presents users with a list of elements derived from the result of a dR View. This approach ensures that the filter prompt displays data based on the underlying SQL query, allowing for dynamic and data-driven filtering.

Hierarchical Filter Type

The **Hierarchical filter type** works as a tree structure, with nodes interacting as parent-child elements. To create hierarchical filters, the source elements must also come from a dR View, allowing for organized and structured filtering.
